

FlightPath Server

Introducing FlightPath Server Data Preboarding Automation

FlightPath Server connects your MFT and data lake, creating a complete preboarding ingestion solution.

What Is Data preboarding?

Preboarding controls vendor and partner data file feeds as they arrive to protect your applications, analytics, and AI.

It is the process of registering, validating, upgrading, and staging trustworthy data. A solid preboarding process can dramatically lower costs, speed time-to-value, and reduce the risks inherent in working with external data. Ingestion without good preboarding is like walking into an unknown restaurant for dinner and saying “surprise me”.

An Automation Architecture

Most data file feeds today are homegrown inefficient and risky. The result is up to 50% of data engineering and operations time is eaten up by firefighting. The FlightPath architecture is a drop-in replacement purpose built to make data preboarding efficient, with little code, pre-integrated components, and no architectural design effort required.

FlightPath Server automates the CsvPath Framework. It connects managed file transfer (MFT) systems to CsvPath Framework. CsvPath

Framework processes files and hands off to the existing data lake and applications. The server enables downstream systems to search for data and metadata. FlightPath Server supports any number of data partner projects, each in their own protected space. For high scalability, lightweight FlightPath Server instances can be spun up on-demand in an on-prem kubernetes or in the cloud.

The Server is paired with the FlightPath Data frontend for Windows or Mac. The app is a DataOps team member’s workspace. Developing and deploying preboarding validation and upgrading scripts becomes even more agile and consistent. And FlightPath Data, working with FlightPath Server, enables team members to perform operations tasks like deploying projects to FlightPath Server.
